Introduction

The 2016, edition of the Cotton Contamination Survey has been published on CD-ROM, to facilitate its distribution and to encourage multi-year comparison of results. Thus, the survey results for the five previous editions, 2005, 2007, 2009, 2011, 2013 and 2016 are included on this CD, and the contents are organized by year and by topic. This structure enables an easy comparison among the six sets of results, in order for readers to track contamination developments in a given cotton description over time.

Foreword

In an effort to shed more light on *spinners' perception* of the problem of cotton contamination and foreign matter, the International Textile Manufacturers Federation (ITMF) has conducted regular surveys since 1982 with spinning mills affiliated to its world-wide membership.

For decades, spinners have produced evidence of all kinds of foreign matter found inside cotton bales which could often be eliminated by hand as long as spinning was still largely a labour-intensive processing technology. Following the extensive modernization of production equipment in recent years, processing steps which previously required the intervention of manual labour are increasingly performed by machines. The trend towards automation in textile manufacturing is not limited to any particular geographical area and will gain further momentum in the years to come.

The biggest problem which automation presents for cotton relates to *cleanliness*. Automated equipment can detect and eliminate contamination or foreign matter only to a limited degree. In the case of plastic material - one of the most vicious forms of contamination - the damage is becoming visible only by the time the fabric leaves the final finishing process, at which stage it is too late to apply any remedy. It is not only affecting the quality and appearance of the final textile product, but may actually damage the processing machinery itself.

By accumulating evidence of contamination and foreign matter at regular intervals, ITMF helps cotton producers, merchants and spinners to better identify problem areas and thus contribute towards their eradication.

December 2016

Methodology

The data used in the survey have been collected by means of a questionnaire which gave spinning companies the possibility of evaluating virtually all cotton descriptions (= combinations of country of origin and name of growth) consumed and traded internationally. An excerpt of the questionnaire showing its legend and four of the pre-indicated descriptions is reproduced on the following page.

It is important to point out some methodological aspects and underlying assumptions before reading the results of the survey.

For each description, participating companies (respondents) were asked to indicate whether or not they had consumed that particular description. This has been done in an attempt to avoid respondents inadvertently "forgetting" descriptions which had been consumed but were not found to be contaminated.

The basic statistical unit (the sample) of this survey is a mill's evaluation of a given description which it had consumed during the last 12 months. It is assumed that no description by the average mill has been consumed to a distorting degree, i.e. in much larger/smaller quantities than each of the other descriptions reported on. If this were not the case, sources of contamination appearing in a discrete, i.e. discontinuous fashion (e.g. metal/wire) might in this survey make descriptions consumed in larger quantities appear "worse" than descriptions consumed in smaller quantities. Nevertheless, in order to technically prevent such a possible bias from having an undue impact on the final results, no distinction has been made between "non-existent" and "insignificant" contamination, the underlying assumption being that respondents who have experienced discrete contamination in a much used description would be inclined to consider it insignificant in relation to the volume consumed.

In the weighting of the 16 sources of contamination, these are all assumed to be equally serious. It is, therefore, important to note that the key summary indicators for each description (the averages of all 16 contaminants combined) are calculated only for the purpose of facilitating general comparisons between different descriptions. Thus, for instance, a low average percentage figure under the category "seriously contaminated" in the summary indicator for a description does not exclude that description from being seriously contaminated by one of the 16 sources indicated. The latter would, however, be clearly visible from the individual table for the description in question.

Moreover, in the introductory summary tables, in which comparisons are made between different descriptions, the ranking has basically been made according to the percentages of replies falling into the category "non-existent/insignificant". However, descriptions with an identical percentage of replies falling into this category have been further ranked according to the percentages of replies falling into the category "serious". In the same summary tables showing a ranking of descriptions, only those descriptions which have been evaluated by at least five respondents have been included.

Finally, concerning stickiness and seed-coat fragments, there do not seem to be any methodologically critical points in the rather simple approach to those two questions in the survey.

Press Release

Summary of Survey Results 2005

Foreign matter, stickiness and seed-coat fragments in raw cotton continue to be among the most serious problems affecting the cotton spinning industry worldwide. This is the conclusion to be drawn from the "Cotton Contamination Survey 2005" which has just been released by the International Textile Manufacturers Federation (ITMF). The survey is carried out every other year, the 2005 edition being the ninth in the series since the changeover to a new methodology in 1989. In the 2005 report, 152 spinning mills located in 18 countries evaluated 68 cotton growths.

Contamination – falling for the first time since 1997

With 22% of all cottons evaluated in 2005 found to be seriously or moderately contaminated, the overall level of contamination fell from 26% in 2003. The cottons evaluated in 2005 were in 7% (2003: 8%) of all cases found to be seriously contaminated by 16 different sources of foreign matter, a further 15% (2003: 18%) were moderately contaminated, leaving 78% (2003: 74%) insignificantly or not at all contaminated. As these summary data are arithmetic averages, the extent of contamination is fully illustrated only by the results for the individual contaminants, which range from 5% for "tar" (2003: 6%) to 40% of all cottons processed being either moderately or seriously contaminated by "organic matter", i.e. leaves, feathers, paper, leather, etc. (down from 50% in 2003). Other serious contaminants are "fabrics" made of cotton, "strings" made of woven plastic and plastic film and "inorganic matter" in the form of sand or dust. Also of concern are, in descending order of incidence, woven plastic and plastic film fabrics, cotton strings, jute/hessian fabrics, and grease or oil. The most contaminated descriptions originate in Turkey, India, Paraguay, Nigeria, Syria and Central Asia. In contrast, very clean cottons can be found in Israel, Senegal, the US, Zimbabwe, Australia and Togo.

Stickiness – on a record low

In the 2005 survey, 17% of all evaluations reveal the presence of stickiness, which is significantly lower compared to 2003 (21%). This short-term decline is in line with the long-term trend of falling levels of stickiness. In 2005, the highest occurrence of stickiness was reported for Cameroon (64%), followed by Sudan (44%), Uzbekistan (medium staple: 39%) and Mali (37%). Of the American growths, California (35%), Pima (31%) and Arizona (31%) were reported to be sticky. On the other hand, no stickiness has been experienced in cotton originating in the South Eastern USA, Zimbabwe, Turkey (Izmir and Turkey-Others), India (Shankar-4/6 and MCU-5), Zambia, Senegal, Spain and Togo.

Seed-coat fragments – improvement

The appearance of seed-coat fragments dropped to the level of the long-run average (37%), a significant improvement compared to the 44% recorded in 2003. The origins most affected were those from Nigeria (100%), India (J-34: 86%), Turkmenistan (long-staple: 83%) and Uzbekistan (long-staple: 71%). Cottons for which the existence of seed-coat fragments was negligible (prevalence of less than 20%) included those from Togo (0%), Zimbabwe (7%), Paraguay (10%), Ivory Coast (14%), USA (Arizona: 15%), Egypt (Giza: 17%), Australia (17%) and China (Xinjiang: 17%) and Israel (Pima: 18%).

Press Release

Summary of Survey Results 2007

Foreign matter, stickiness and seed-coat fragments in raw cotton continue to be serious challenges to the cotton spinning industry worldwide. This is the general conclusion to be drawn from the "Cotton Contamination Survey 2007" which has just been released by the International Textile manufacturers Federation (ITMF). The survey is carried out every other year, the 2007 edition being the tenth in the series since the changeover to a new methodology in 1989. In the 2007 report, 114 spinning mills located in 23 countries evaluated 72 different cotton growths.

Contamination – unchanged in comparison to 2005

The level of cottons modestly or seriously contaminated as perceived by the spinning mills from around the world did not increase compared to the last survey in 2005 remaining constant at 22%. A closer look at the extent of the contamination shows that 7% (2005: 7%) of all cotton evaluated were seriously contaminated by some sort of foreign matter whereas 15% (2005: 15%) were only moderately contaminated. As the summary data are arithmetic averages, the extent of contamination is fully illustrated only by the results for the individual contaminants. They range from 5% for "tar" (2005: 5%) to 40% of all cottons processed being contaminated by organic matter, i.e. leaves, feathers, paper, leather, etc. (2005: 40%). With respect to the extent of contamination through "organic matter" it is worthwhile noting that the degree of contamination increased nevertheless due to the fact that more cottons were affected seriously (2007: 13% versus 2005: 8%) and less moderately (2007: 27% versus 2005: 32%) compared to the last survey. Other serious contaminants are fabrics made of plastic film or cotton (30% each) and strings made of plastic film or jute/hessian (29% each). The most contaminated cotton descriptions originated in India, Togo, Turkey, Mali and Uzbekistan. In contrast, very clean raw cottons were produced in the USA (Memphis, Texas High Plains, Others, South Eastern, California, Pima), Australia, Israel, Brazil and Cameroon.

Stickiness – on the rise again

The presence of sticky cotton as perceived by the spinning mills increased in 2007 to 21% after having fallen to 17% in 2005, the lowest level since 1989. This level of stickiness is in line with the long-term average and shows that stickiness remains a major challenge to the spinning industry. Descriptions that were affected most by stickiness were those from Benin, Cameroon and Uzbekistan (medium staples). Also US cotton growths like USA-Others, Pima and California were reported to be sticky. On the other hand, cottons from Greece, India (H-4 and Others), Turkey (Izmir), Egypt (Giza) or Zimbabwe as well as US cotton growths like South Eastern or Texas High Plains were not or hardly affected by stickiness.

Seed-coat fragments – remained on the long-term average

With regard to seed-coat fragments the Cotton Contamination Survey 2007 shows that their appearance in cotton growths remained an issue for the spinners around the world with 37% claiming that they have encountered them in the cotton growths consumed. This is the same level as reached in 2005 and is equivalent to the long-term average. The origins affected most by seed-coat fragments are those from India (LRA, J-34, Others), Uzbekistan (medium staples), Chad, Benin, Turkmenistan (medium staples) and Ivory Coast. Cotton descriptions for which the existence of seed-coat fragments was negligible (prevalence of less than 25%) included those from the US (Texas High Plains, California, Arizona, Others, Pima), Australia, Egypt (Giza), Greece and Cameroon.

Press Release

Summary of Survey Results 2009

“Despite some improvements in the recent past foreign matter, stickiness and seed-coat fragments in raw cotton continue to be serious challenges to the cotton spinning industry worldwide.” This is the general conclusion to be drawn from the “Cotton Contamination Survey 2009” which has just been released by the International Textile Manufacturers Federation (ITMF). The survey is carried out every other year, the 2009 edition being the eleventh in the series since the changeover to a new methodology in 1989. In the 2009 report, 110 spinning mills located in 23 countries evaluated 63 different cotton growths.

Contamination – unchanged in comparison to 2007

The level of cottons modestly or seriously contaminated as perceived by the spinning mills from around the world did not increase compared to the last survey in 2007 remaining constant at 22%. A closer look at the extent of the contamination shows that 6% (2007: 7%) of all cotton evaluated were seriously contaminated by some sort of foreign matter whereas 16% (2007: 15%) were only moderately contaminated. As the summary data are arithmetic averages of the different contaminants, the extent of contamination is fully illustrated only by the results for the individual contaminants. They range from 4% for “tar” (2007: 5%) to 42% of all cottons processed being contaminated by “organic matter”, i.e. leaves, feathers, paper, leather, etc. (2007: 40%). Other serious contaminants are “strings made of jute hessian” (32%), “strings made of woven plastic” (29%), “fabrics made of cotton” as well as “fabrics made of plastic film” and “strings made of cotton” (26% each). The most contaminated cotton descriptions considered for the survey originated in India, Pakistan, Egypt, Uzbekistan and Mali. In contrast, very clean raw cottons were produced in the USA, (Texas High Plains, Memphis, Pima, South Eastern, California), Israel, Australia, Brazil and the Ivory Coast.

Stickiness – record low

The presence of sticky cotton as perceived by the spinning mills fell in 2009 to 16%, the lowest level ever recorded (compared to 21% in 2007). Nevertheless, the level of stickiness is still considerable high and remains a major challenge to the spinning industry. Descriptions that were affected most by stickiness were those from Burkina Faso, Benin, Brazil, Chad, and Uzbekistan (medium staples). Also US cotton growths like US-Pima, Israel-Pima, Mali or Tajikistan (medium staples) were reported to be sticky. On the other end of the range, cottons from Egypt, Greece, USA (California, South Eastern), Australia, Ivory Coast, Nigeria, and Pakistan (AmSeed AFZAL, Others) or India (Shankar-4/6, MCU-5) were not or hardly affected by stickiness.

Seed-coat fragments – lowest level recorded since introduction in 1991

With regard to seed-coat fragments the Cotton Contamination Survey 2009 shows that their appearance in cotton growths remained an issue for spinners around the world with 31% claiming that they have encountered them in the cotton growths consumed. This is the lowest level since including measuring the level of seed-coat fragments in the survey in 1991. The origins affected most by seed-coat fragments are those from Nigeria, India (H-4, J-34), USA (South Eastern), Uzbekistan (medium staples), Tajikistan (medium staples), Burkina Faso and Syria. Cotton descriptions for which the existence of seed-coat fragments was negligible (prevalence of less than 20%) included those from Australia, Benin, India (Others), Pakistan (Others), and the US (California, Texas High Plains).

Press Release

Summary of Survey Results 2011

"After some improvements in the recent past foreign matter, stickiness and seed-coat fragments in raw cotton pose serious challenges to the cotton spinning industry worldwide." This is the general conclusion to be drawn from the "Cotton Contamination Survey 2011" which has just been released by the International Textile Manufacturers Federation (ITMF). The survey is carried out every other year, the 2011 edition being the twelfth in the series since the changeover to a new methodology in 1989. In the 2011 report, 119 spinning mills located in 24 countries evaluated 71 different cotton growths.

Contamination – slight increase

The level of cottons modestly or seriously contaminated as perceived by the spinning mills from around the world rose slightly from 22% to 23% compared to the last survey in 2009. A closer look at the extent of the contamination shows that 7% (2009: 6%) of all cotton evaluated were seriously contaminated by some sort of foreign matter whereas 16% (2009: 15%) were only moderately contaminated. As the summary data are arithmetic averages of the different contaminants, the extent of contamination is fully illustrated only by the results for the individual contaminants. They range from 5% for "tar" (2009: 4%) to 51% of all cottons processed being moderately or seriously contaminated by "organic matter", i.e. leaves, feathers, paper, leather, etc. (2009: 42%). Other serious contaminants are "inorganic matter" (31%), "fabrics made of cotton" (30%), "strings made of woven plastic" (29%) as well as "fabrics made of woven plastic" and "strings made of plastic film" (28% each). The most contaminated cotton descriptions considered for the survey originated in India, Nigeria, Zimbabwe, China and Turkey. In contrast, very clean raw cottons were produced in the USA, (Texas High Plains, Arizona, Pima, USA-Others, Memphis and California), Syria, Benin, Brazil, Spain, Argentina, Greece and Australia).

Stickiness – significant rise

The presence of sticky cotton as perceived by the spinning mills increased in 2011 significantly from the record low of 16% in 2009 to 20%. While this level is still lower than the long-term average, the level of stickiness is still considerable high and remains a major challenge to the global cotton spinning industry. Descriptions that were affected most by stickiness were those from India (DCH, MCU-5, India-Others), Syria, USA (California, Pima), Spain, Mali and Uzbekistan (Medium-Staples. On the other end of the range, cottons from Argentina, Turkey (Izmir), USA (Arizona), Egypt (Giza), India (J-34) and USA (Texas High Plains) were not or hardly affected by stickiness.

Seed-coat fragments – noticeable jump

With regard to seed-coat fragments the Cotton Contamination Survey 2011 shows that their appearance in cotton growths remains an issue for spinners around the world. 38% of cotton spinners (2009: 31%) claim that they have encountered seed-coat fragments in the cotton growths consumed. This is a jump of 7 percentage points, up from only 31% in 2009, the lowest level since including measuring the level of seed-coat fragments in the survey in 1991. The origins affected most by seed-coat fragments are those from Nigeria, India (India-Others, MCU-5, Shankar-4/6, J-34) USA (South Eastern, California), Ivory Coast and Turkey (Turkey-Others). Cotton descriptions for which the existence of seed-coat fragments was negligible (prevalence of less than 20%) included those from Australia, Benin, India (Others), Pakistan (Others), and the US (California, Texas High Plains).

Press Release

Summary of Survey Results 2013

"After some improvements in the recent past foreign matters, stickiness and seed-coat fragments in raw cotton pose serious challenges to the cotton spinning industry worldwide."

This is the general conclusion to be drawn from the "Cotton Contamination Survey 2013" which has just been released by the International Textile Manufacturers Federation (ITMF). The survey is carried out every other year, the 2013 edition being the thirteenth in the series since the changeover to a new methodology in 1989. In the 2013 report, 119 spinning mills located in 24 countries evaluated 73 different cotton growths.

Contamination – slight increase

The level of cottons moderately or seriously contaminated as perceived by the spinning mills from around the world rose from 23% to 26% compared to the last survey in 2011. A closer look at the extent of the contamination shows that 8% (2011: 7%) of all cotton evaluated were seriously contaminated by some sort of foreign matter whereas 18% (2011: 16%) were only moderately contaminated. As the summary data are arithmetic averages of the different contaminants, the extent of contamination is fully illustrated only by the results for the individual contaminants. They range from 7% for "tar" (2011: 5%) to 55% of all cottons processed being moderately or seriously contaminated by "organic matter", i.e. leaves, feathers, paper, leather, etc. (2011: 51%). Other serious contaminants are "strings made of cotton" (38%), "strings made of woven plastics" (36%), "fabrics made of cotton" (36%) as well as "strings made of jute/hessian" (34%). The most contaminated cotton descriptions considered for the survey originated in India (DCH, Shankar-4/6, MCU-5, J-34, India-Others), Zambia, Pakistan (Pakistan Others), Tajikistan (Medium Staples), Uzbekistan (Medium Staples) and China (Xinjiang). In contrast, very clean raw cottons were produced in USA, (California, USA-Others, Memphis Territory, South Eastern and Pima), Spain, Australia, Brazil, Togo and Benin.

Stickiness – significant rise

The presence of sticky cotton as perceived by the spinning mills increased again in 2013 significantly from 20% in 2011 to 23%. This level is higher than the long-term average. Therefore, stickiness remains a major challenge to the global cotton spinning industry. Descriptions that were affected most by stickiness were those from Uzbekistan (Medium Staples), Turkmenistan (Medium Staples), Togo, Mozambique, Chad, Burkina Faso, Tajikistan (Medium Staples), Mali, Ivory Coast and China (Xinjiang). On the other end of the range, cottons from USA (Texas High Plains, California, South Eastern), India (J-34, MCU, India-Others), Zambia, Pakistan (Others) and Egypt (Giza) were not or hardly affected by stickiness.

Seed-coat fragments – noticeable jump

With regard to seed-coat fragments the Cotton Contamination Survey 2013 shows that their appearance in cotton growths remains an issue for spinners around the world. 42% of cotton spinners (2011: 38%) claim that they have encountered moderate or significant amounts of seed-coat fragments in the cotton growths consumed. This is a jump of 11 percentage points since the all-time low of 31% in 2009. The origins affected most by seed-coat fragments are those from Nigeria, India (H-4, J-34, Shankar-4/6, MCU-5, India-Others), Pakistan-Others, Argentina, Mozambique and Zambia. Countries for which the existence of seed-coat fragments was negligible (prevalence of less than 30%) included those from USA (California, South Eastern, Texas High Plains, Pima, Memphis Territory, USA-Others), Spain, Benin, Australia and Burkina Faso.

Participation

Press Release

Summary of Survey Results 2016

"Raw cotton has become cleaner. ITMF's Cotton Contamination Survey shows that the level of contamination of raw cotton by foreign matters has fallen in 2016. The level of contamination, however, remains high and poses a serious challenge for the cotton spinning industry. The survey also shows that the level of stickiness and the appearance of seed-coat fragments have fallen significantly in 2016 compared to the previous survey from 2013." This is the general conclusion to be drawn from the "Cotton Contamination Survey 2016" which has just been released by the International Textile Manufacturers Federation (ITMF). The 2016 edition is the fourteenth in the series since the changeover to a new methodology in 1989. In the 2016 report, 90 spinning mills located in 22 countries evaluated 71 different cotton growths.

Contamination – slight decrease

The level of cottons moderately or seriously contaminated as perceived by the spinning mills from around the world fell from 26% to 23% compared to the last survey in 2013. A closer look at the extent of the contamination shows that 5% (2013: 8%) of all cotton evaluated were seriously contaminated by some sort of foreign matter whereas 18% (2013: 18%) were only moderately contaminated. As the summary data are arithmetic averages of the different contaminants, the extent of contamination is fully illustrated only by the results for the individual contaminants. They range from 5% for "tar" to 47% of all cottons processed being moderately or seriously contaminated by "organic matter", i.e. leaves, feathers, paper, leather, etc. Other serious contaminants are "fabrics made of plastic film" (38%), "strings made of woven plastic" (31%), "fabrics made of woven plastic" (31%) as well as "sand and dust" (31%). The most contaminated cotton descriptions considered for the survey originated in India (DCH, Shankar-4/6, MCU-5, J-34, India-Others), Pakistan (Pakistan Others), Uzbekistan (Medium Staples) and Ivory Coast. In contrast, very clean raw cottons were produced in Australia, Brazil, the USA, (Arizona, California, USA-Others, Memphis Territory, South Eastern and Pima) and China (Shandong, Xinjiang).

Stickiness – significant fall

The presence of sticky cotton as perceived by the spinning mills fell in 2016 significantly from 23% in 2013 to 16%, the lowest level since 2009. Descriptions that were affected most by stickiness were those from Brazil, India (DCH, MCU-5, India Others), the USA (Arizona, California, Pima and South Eastern), Spain and Pakistan (Pakistan Others). On the other end of the range, cottons from China (Hebei, Henan, Hubei, Shandong), Cameroon, Argentina and Benin were not or hardly affected by stickiness.

Seed-coat fragments – noticeable decline

With regard to seed-coat fragments the Cotton Contamination Survey 2016 shows that their appearance in cotton growths remains an issue for spinners around the world though the level of contamination fell significantly. 32% of cotton spinners (2013: 42%) claim that they have encountered moderate or significant amounts of seed-coat fragments in the cotton growths consumed, the lowest level since 2009. The origins affected most by seed-coat fragments are those from India (DCH, J-34, Shankar-4/6, MCU-5, India-Others), Pakistan-Others, Mali and Turkey (Izmir). Countries for which the existence of seed-coat fragments was negligible (prevalence of less than 30%) included those from the USA (Arizona, California, Pima, USA-Others), Australia, China (Hebei, Henan, Hubei, Shandong) and Burkina Faso.
